### Department of Artificial Intelligence & Data Science

Aim: To implement Naïve Bayesian classification

#### **Objective**

Develop a program to implement a Decision Tree classifier.

#### Theory

Decision Tree is a popular supervised learning algorithm used for both classification and regression tasks. It operates by recursively partitioning the data into subsets based on the most significant attribute, creating a tree structure where leaf nodes represent the class labels.

#### **Steps in Decision Tree Classification:**

- 1. **Tree Construction**: The algorithm selects the best attribute of the dataset at each node as the root of the tree. Instances are then split into subsets based on the attribute values.
- 2. **Attribute Selection**: Common metrics include Information Gain, Gini Index, or Gain Ratio, which measure the effectiveness of an attribute in classifying the data.
- 3. **Stopping Criteria**: The tree-building process stops when one of the stopping criteria is met, such as all instances in a node belonging to the same class, or when further splitting does not add significant value.
- 4. **Classification Decision**: New instances are classified by traversing the tree from the root to a leaf node, where the majority class determines the prediction.

#### **Example**

Given a dataset with attributes and corresponding class labels:

- Construct a decision tree by recursively selecting the best attributes for splitting.
- Use the tree to classify new instances by traversing from the root to the appropriate leaf node.

#### Code:

#Decision Tree
import pandas as pd
from sklearn.model\_selection import train\_test\_split
from sklearn.tree import DecisionTreeClassifier
from sklearn.metrics import accuracy\_score, classification\_report, confusion\_matrix

#Split data into training and testing sets

X train, X test, y train, y test = train test split(X, y, test size=0.2, random state=42)

#Initialize DecisionTreeClassifier clf = DecisionTreeClassifier(random state=42)

#Train the classifier

# Vidyavardhini's College of Engineering and Technology

### Department of Artificial Intelligence & Data Science

```
clf.fit(X_train, y_train)

#Make predictions
y_pred = clf.predict(X_test)

# Evaluate the model
accuracy = accuracy_score(y_test, y_pred)
precision = precision_score(y_test, y_pred)
recall = recall_score(y_test, y_pred)
roc_auc = roc_auc_score(y_test, knn_model.predict_proba(X_test)[:, 1])
classification_rep = classification_report(y_test, y_pred)

print(f'Accuracy: {accuracy}')
print(f'Precision: {precision}')
```

Score:

#### Output:

print(f'ROC

print(f'Recall: {recall}')

AUC

print(fClassification Report:\n{classification rep}')

Predict the class label for new instances based on the constructed decision tree.

{roc auc}')

#### Conclusion

Describe techniques or modifications to decision tree algorithms that can address issues caused by class imbalance in datasets.

To handle class imbalance in decision trees, you can:

- 1. Class Weight Adjustment: Assign higher weights to minority classes using the 'class\_weight='balanced' parameter.
- 2. Resampling: Use oversampling (e.g., SMOTE) or undersampling to balance the dataset.
- 3. Ensemble Methods: Implement techniques like Balanced Random Forest or EasyEnsemble for better handling of imbalanced data.
- 4. Cost-sensitive Learning: Apply higher costs to misclassifying minority classes.
- 5. Pruning: Limit tree depth and size to prevent overfitting to the majority class.
- 6. Optimize Metrics: Focus on precision, recall, and F1-score rather than overall accuracy.
